Project Architecture
Splitting Code into Logical Parts

Splitting Code into Methods (1)

- We use **methods** to split code into functional blocks

  - Improves code **readability**

  - Allows for easier **debugging**

```
for (char move : moves){
    for (int r = 0; r < room.length; r++)
        for (int c = 0; c < room[r].length; c++)
            if (room[row][col] == 'b')
                …
}
```

```
for (char move : moves) {

    moveEnemies();

    killerCheck();

    movePlayer(move);

}
```

Splitting Code into Methods (2)

- **Methods** let us easily **reuse** code

- We change the **method** once to affect **all calls**

```
BankAccount bankAcc = new BankAccount();

bankAcc.setId(1);

bankAcc.deposit(20);

System.out.printf("Account %d, balance %d",
                  bankAcc.getId(),bankAcc.getBalance());
bankAcc.withdraw(10);
…
System.out.println(bankAcc.ToString());
```

Override `.toString()` to set a global printing format

Splitting Code into Methods (3)

- A **single** method should complete a **single task**

```
void doMagic ( … )

void depositOrWithdraw ( … )

BigDecimal depositAndGetBalance ( … )

String parseDataAndReturnResult ( … )
```

```
void withdraw ( … )

void deposit ( … )

BigDecimal getBalance ( … )

string toString ( … )
```

Problem: Rhombus of Stars

- Draw on the console a rhombus of stars with size **n**

```
n = 3

      *
    *   *
  *   *   *
    *   *
      *
```
```
n = 2

    *
  *   *
    *
```

```
n = 1

  *
```

Check your solution here : https://judge.softuni.bg/Contests/1575/Working-with-Abstraction-Lab

Solution: Rhombus of Stars (1)

```java
int size = Integer.parseInt(sc.nextLine());
for (int starCount = 1; starCount <= size; starCount++) {
    printRow(size, starCount);
}
for (int starCount = size - 1; starCount >= 1; starCount--) {
    printRow(size, starCount);
}
```

Reusing code

Check your solution here : https://judge.softuni.bg/Contests/1575/Working-with-Abstraction-Lab

Solution: Rhombus of Stars (2)

```java
static void printRow(int figureSize, int starCount) {

  for (int i = 0; i < figureSize - starCount; i++)

    System.out.print(" ");

  for (int col = 1; col < starCount; col++) {

    System.out.print("* ");

  }

  System.out.println("*");

}
```

Check your solution here : https://judge.softuni.bg/Contests/1575/Working-with-Abstraction-Lab

Splitting Code into Classes (1)

- Just like methods, **classes** should **not** know or do too much

```
GodMode master = new GodMode();

int[] numbers = master.parseAny(input);

...

int[] numbers2 = master.copyAny(numbers);

master.printToConsole(master.getDate());

master.printToConsole(numbers);
```

Splitting Code into Classes (2)

- We can also break our code up logically into **classes**

```java
List<Integer> input = Arrays.stream(
        sc.nextLine().split(" "))
        .map(Integer::parseInt)
        .collect(Collectors.toList());
...
String result = input.stream()
                .map(String::valueOf)
                .collect(Collectors.joining(", "));
System.out.println(result);
```

```java
ArrayParser parser = new ArrayParser();
OuputWriter printer = new OuputWriter();
int[] numbers = parser.integersParse(args);
int[] coordinates = parser.integerParse(args1);
printer.printToConsole(numbers);
```

Hiding implementation

Allow us to change output destination

Helps us avoid repeating code

Problem: Point in Rectangle

- Create a Point class holding the horizontal and vertical coordinates

- Create a **Rectangle class**

  - Holds 2 **points**

    - **Bottom left** and **top right**

- Add **Contains** method

  - Takes a **Point** as an argument

  - **Returns** it if it's inside the current object of the **Rectangle class**

Check your solution here :https://judge.softuni.bg/Contests/1575/Working-with-Abstraction-Lab

Solution: Point in Rectangle

```java
public class Point {
    private int x;
    private int y;
    //TODO: Add getters and setters
}
public class Rectangle {
    private Point bottomLeft;
    private Point topRight;
    //TODO: getters and setters
    public boolean contains(Point point) {
        //TODO: Implement

    }
}
```

Check your solution here : https://judge.softuni.bg/Contests/1575/Working-with-Abstraction-Lab

Solution: Point in Rectangle (2)

```java
public boolean contains(Point point)
{
    boolean isInHorizontal =
        this.bottomLeft.getX() <= point.getX() &&
        this.topRight.getX() >= point.getX();

    boolean isInVertical =
        this.bottomLeft.getY() <= point.getY() &&
        this.topRight.getY() >= point.getY();

    boolean isInRectangle = isInHorizontal &&
                            isInVertical;

    return isInRectangle;
}
```

Check your solution here : https://judge.softuni.bg/Contests/1575/Working-with-Abstraction-Lab

Refactoring
Restructuring and Organizing Code

Refactoring

- **Restructures** code without changing the behaviour

- **Improves** code readability

- **Reduces** complexity

```
class ProblemSolver { public static void doMagic() { … } }
```

```
class CommandParser {
    public static <T> Function<T, T> parseCommand() { … } }
class DataModifier { public static <T> T execute() { … } }
class OutputFormatter { public static void print() { … } }
```

Refactoring Techniques

SoftUni Foundation

- **Breaking code** into reusable units

- **Extracting parts of methods** and **classes** into **new** ones

`depositOrWithdraw()` ➡ `deposit()` `withdraw()`

- **Improving names** of variables, methods, classes, etc.

`String str;` ➡ `String name;`

- **Moving methods** or **fields** to more appropriate classes

`Car.open()` ➡ `Door.open()`

Problem: Student System

- You are given a **working** Student System project to refactor

- **Break it up** into smaller functional units and make sure it works

- It supports the following **commands**:

  - "Create <studentName> <studentAge> <studentGrade>"

    - creates a new student

  - "Show <studentName>"

    - prints information about a student

  - "Exit"

    - closes the program

  Check your solution here : https://judge.softuni.bg/Contests/1575/Working-with-Abstraction-Lab
Enumerations
Syntax and Usage

Enumerations

- Represent a numeric value from a fixed set as a text

- We can use them to pass **arguments** to **methods** without making code confusing

```
enum Day {Mon, Tue, Wed, Thu, Fri, Sat, Sun}
```

```
GetDailySchedule(0)      ➡      GetDailySchedule(Day.Mon)
```
- By default **enums** start at 0

- Every next value is incremented by 1

- We can **customize** enum **values**

```java
enum Day {

  Mon(1),Tue(2),Wed(3),Thu(4),Fri(5),Sat(6),Sun(7);

  private int value;

  Day(int value) {
    this.value = value;
  }
}

System.out.println(Day.Sat); // Sat
```

- We can **customize** enum **values**

```java
enum CoffeeSize {
    Small(100), Normal(150), Double(300);

    private int size;

    CoffeeSize(int size) {
        this.size = size;
    }

    public int getValue() { return this.size; }
}

System.out.println(CoffeeSize.Small.getValue()); // 100
```

Problem: Hotel Reservation

- Create a class PriceCalculator that calculates the total price of a holiday, by given **price per day**, **number of days**, **the season** and a **discount type**

- The discount type and season should be **enums**

- The price multipliers will be:

    - 1x for Autumn, 2x for Spring, etc.

- The discount types will be:

    - None – 0%

    - SecondVisit – 10%

    - VIP – 20%

Solution: Hotel Reservation (1)

```java
public enum Season {

    Spring(2), Summer(4), Autumn(1), Winter(3);

    private int value;

    Season(int value) {

        this.value = value;

    }

    public int getValue(){

        return this.value;

    }

}
```

Check your solution here : https://judge.softuni.bg/Contests/1575/Working-with-Abstraction-Lab

Solution: Hotel Reservation (2)

```java
public enum Discount {

    None(0), SecondVisit(10), VIP(20);

    private int value;

    Discount(int value) {

        this.value = value;

    }

    public int getValue() {

        return this.value;

    }

}
```

Check your solution here :https://judge.softuni.bg/Contests/1575/Working-with-Abstraction-Lab

Solution: Hotel Reservation (3)

```java
public class PriceCalculator {
  public static double CalculatePrice(double pricePerDay,
             int numberOfDays, Season season, Discount discount) {
    int multiplier = season.getValue();
    double discountMultiplier = discount.getValue() / 100.0;
    double priceBeforeDiscount = numberOfDays * pricePerDay * multiplier;
    double discountedAmount = priceBeforeDiscount * discountMultiplier;
    return priceBeforeDiscount - discountedAmount;
  }
}
```

Check your solution here : https://judge.softuni.bg/Contests/1575/Working-with-Abstraction-Lab

Static Keyword in Java
Static Class, Variable, Method and Block

Static Keyword

- Used for memory management mainly

- Can apply with:

  - Nested class

  - Variables

  - Methods

  - Blocks

```
static int count;
static void increaseCount() {
    count++;
}
```

- Belongs to the class than an instance of the class

Static Class

- A **top level** class is a class that is not a nested class

- A **nested** class is any class whose declaration occurs within the body of another class or interface

- Only nested classes can be **static**

```
class TopClass {

    static class NestedStaticClass {

    }
}
```

Static Variable

- Can be used to refer to the **common** variable of all objects

- For example

  - The company name of employees

  - College name of students

    - Name of the college is common for all students

- Allocate memory only once in class area at the timeof class loading

```java
class Counter {
  int count = 0;    static int staticCount = 0;
  public Counter() {
    count++;          // incrementing value
    staticCount++;   // incrementing value
  }
  public void printCounters() {
    System.out.printf("Count: %d%n", count);
    System.out.printf("Static Count: %d%n", staticCount);
  }
}
```

```
// Inside the Main Class
public static void main(String[] args) {
    Counter c1 = new Counter();
    c1.printCounters();
    Counter c2 = new Counter();
    c2.printCounters();
    Counter c3 = new Counter();
    c3.printCounters();
    int counter = Counter.staticCount; // 3
}
```

Count: 1

Static Count: 1

Count: 1

Static Count: 2

Count: 1

Static Count: 3

Static Method

- Belongs to the class rather than the object of a class

- Can be **invoked** without the need for creating an instance of a class

- Can **access** static data member and can **change** the value of it

- Can **not use non-static** data member or call **non-static method** directly

- **this** and **super** cannot be used in static context
```java
class Calculate {
    static int cube(int x) { return x * x * x; }
    public static void main(String args[]) {
        int result = Calculate.cube(5);
        System.out.println(result);            // 125
        System.out.println(Math.pow(2, 3)); // 8.0
    }
}
```

Static Block

- A set of **statements**, which will be executed by the JVM before execution of `main` method

- Executing **static block** is at the time of class loading

- A class can take any number of static block but all blocks will be execute **from top to bottom**

```
class Main {

    static int n;

    public static void main(String[] args) {

        System.out.println("From main");

        System.out.println(n);

    }

    static {

        System.out.println("From static block");

        n = 10;

    }

}
```

```
From static block

From main

10
```

Packages
Built-In and User-Defined Packages

Packages in Java

- Used to group related classes
  - Think of it as a folder in a file directory
- Use packages to avoid name conflicts, and to write a better maintainable code
- Packages are divided into two categories:
  - **Built-in Packages** (packages from the **Java API**)
 - User-defined Packages (create own packages)

Build-In Packages

- The library is divided into packages and classes

- Can either import a single class or a whole package that contain all the classes

- To use a class or a package from the library, need to use the import keyword

- The complete list can be found at Oracles website: https://docs.oracle.com/en/java/javase/

```java
import package.name.Class; // Import a single class
import package.name.*;      // Import the whole package
```

Summary

- Well organized code is easier to work with

- We can reduce complexity using **Methods**, **Classes** and **Projects**

- We can refactor existing code by **breaking code apart**

- **Enumerations** define a fixed **set of constants**
    - Represent **numeric values**
    - We can easily **cast enums** to **numeric types**

- **Static** members and **Packages**
